SWTPC PR-40
ALPHANUMERIC PRINTER

* SWTPC PR-40 ALPHANUMERIC PRINTER *

* 40 CHARACTERS / LINE
* 5 X 7 DOT MATRIX IMPACT PRINT
* USES STANDARD 3 7/8" CALCULATOR PAPER
* 75 LINE / MINUTE PRINT RATE
* AUTOMATIC RIBBON REVERSE
* 64 CHARACTER ASCII CHARACTER SET
* 40 CHARACTER LINE MEMORY
* TTL, SWTPC 6800, MITS COMPATIBLE

Ever since the microcomputer's introduction, computer hobbyists everywhere have been searching for a low cost alphanumeric printer. Well, the search is over because here it is! The unit presented here is a 5 X 7 dot matrix impact printer similar in operation to the well known Centronics printers. It prints the 64 character upper case ASCII set with 40 characters/line at a rate of 75 lines/minute on standard 3 7/8" wide rolls of adding machine paper. One complete line is printed at a time from an internal forty character line buffer memory. Printing takes place either on receipt of a carriage return or automatically whenever the line buffer memory is filled.

The printer can accept character data as fast as one character per micro-second or as slow as you wish to send it. The printer's seven parallel data lines are TTL compatible and may be enabled by a single "data ready" control line or by separate "data ready" and "data accepted" handshake control lines. This universal approach makes the printer compatible with all computer and terminal systems having an eight bit parallel interface; including of course the MITS 8800 and SWTPC 6800 computer systems just to mention a few.

The printer mechanism is attached to a black anodized aluminum chassis with front rim panel which houses the unit's circuitry including its own 120/240 VAC 50 to 60 Hz power supply making the printer's overall dimentions 9 5/8" wide X 10 1/2" deep X 8 3/4" high.

The Mechanics

The entire design is based on a remarkably simple and hence more reliable print mechanism. The printed characters are formed by moving the print head horizontally across the paper while selectively operating solenoid driven print wires on the head which strike a

driven print wires converge at the tip of the print head in a vertical line which is perpendicular to the horizontal direction of movement of the print head. By selectively firing the print wires, 5 dot wide X 7 dot high characters are printed as the print head moves across the paper. A one dot time spacing is left for separation between the printed characters.

This method of printing characters is not new but the method of moving this wire impact print head is unique. Rather than using dual motors, clutches timing bars and the other hardware often associated in operating this type of print head, this printer rotates a long cylinder just beneath the print head. The length of the cylinder itself is a little longer than the head's printing width on the paper. The cylinder has a uniform single cyclic zig-zag track formed on its outer circumference, running from the left side of the cylinder to the right side and then back to the left again. A small projection on the bottom of the print head rides in this track so that as the cylinder rotates, the print head moves back and forth from left to right. This technique moves the print head across the paper at a constant velocity except at operation at the extreme ends of course, where nothing is printed anyway. This approach greatly simplifies the electronics needed to drive the printer since no head positioning circuitry is necessary. The cylinder itself is turned by an AC motor on the lower right hand side of the print mechanism. A small ribbed nylon belt interconnecting the two rides on gear teeth of both the motor and cylinder. Also attached to the right side of the cylinder is a cam that actuates a roller arm micro-switch riding on the cam. This is how the printer's electronic circuitry senses the "start of line" position of the print head. On the left side of the cylinder is an eccentric driven pawl arm that advances the paper one line for each revolution of the cylinder which is the same as one cycle of the print head.
Let's go thru a cyclic operation of a printed line where we will first assume the head is in rest position just left of center. When a line print command is initiated by the control circuitry, the motor starts and the head begins to move from the center position toward the far left side of the printer where the head reverses direction. This non-print dead zone gives the motor, cylinder, and print head time to attain full speed. As the head begins its movement from left to right, the cam actuated micro-switch opens telling the electronic circuitry to start outputting character forming solenoid driving pulses. Somewhere before the print head reaches the far right hand edge of the paper the solenoid pulses will cease while the head continues to move. When the head reaches the right end of its travel, it will reverse direction and begin to move back toward the center of the printer. During this return movement, the pawl arm will rotate the platen one line for the line feed. The motor is then turned off just to the left of center where it started originally. Character data is not accepted by the printer's circuitry during an actual print cycle, however feeding continual print data from a computer to the printer may take place so fast that the print motor may never appear to stop between

Some additional comments on the PI-1 adapter:

When the PR-40 is used with the Southwest Computer system,
an interface board is required in the computer. Several
people have written to ask if this board is required to use
the PR-40 with the PET. The answer is no, all you need is
the PI-1 adapter. If the PR-40 has been built to work with
The SWTP interface board, the connecter on the end of the
printer cable plugs directly into the PI-1.

As near as we can find, when the PET closes a file under
program control, some sort of error condition exists. If
anyone can shed further light on this, we would appreciate
hearing from them. In the meantime, we are indebted to
Dr. Joseph Shultz of Hudson, NY, (a PR-40/PET enthusiast),
for the "fix" using the GET function, shown on line 70 of
the printout on the other side of these notes. If this
line of code is added following a CLOSE FILE, the PET does
a proper close, and continues execution of the program at
the line called in the GET statement.

We frequently get requests for a source of used PR-40
printers. Probably the best source is ON LINE, a classi-
fied ad computer hobbiest publication from Dave Beetle,
24695 Santa Cruz Hwy., Los Gatos, CA, 95030. It runs
over 20 pages of classifieds, and Dave has a special trial
subscription of four issues for a dollar.

Many dealers are discounting the PR-40 kit, among them
is Computer Lab of New Jersey, 141 Route 46, Budd Lake,
NJ 07828. Their price is $220 for the kit, and they accept
Master Charge and Visa by phone, at (201) 691-1984.

The PI-1 was developed by Gordon Jones, a member of the
Amateur Computer Group of New Jersey, who was later per-
suaded to produce them in response to numerous requests.
We have been very pleased with the response on this unit,
(including a long-distance ecstatic "thank you" from a
customer in Florida), and are looking forward to working
up additional low-cost peripherals for the PET.

Two things that were problems were the cost of developing
the printed circuit board, which accounts for what we feel
is a rather high price for the PI-1; the other is the matter
of waiting for checks to clear. Based on past experience,
we have to hold orders for about two weeks before shipping,
unless the check is certified, or a postal money order is
used, in which case we ship next day.

In line 9, there are four spaces following the first
set of quote marks; these are valid spaces, but they
should be followed by CLEAR SCREEN, (a reverse heart),
then CURSOR DOWN, (a reverse Q). When a listing is
wanted for reproduction, the program may be edited on
the screen before printing it, to add extra spaces
where necessary so the symbols can be inserted by hand.
For utility purposes, jotting notes to the right of the
listing should suffice.

The other idiosyncracy has to do with the fact that the
printer runs at a net speed of about 50 characters per
second, including time for the head to return to the
left side, whereas the PET appears to output data via
the IEEE port at about 20 characters per second. The
result is that the printhead pauses on the return stroke
for about a second, while waiting for the printer
buffer to fill. The net speed is about 15 characters
per second, but the pause between lines was a little
disconcerting at first.
DESCRIPTION:

The Sigma Interface was developed out of the need for a hard copy output from the PET, at a reasonable cost. It is a small circuit board, with two integrated circuits, and plugs into the IEEE port of the PET via a connector secured to the board. Also mounted on the board is a female molex connector which accepts the connector normally used on the Southwest Technical Products PR-40 printer cable. Power to operate the ICs can be obtained from either the PET or the printer, and provision has been made to allow for operation from an external power source (such as batteries), in cases where it is not desirable to run a wire into the equipment. (This might be the case, for example, when the interface is being used with borrowed equipment.)
THE PR-40 PRINTER:

A comprehensive description of the printer is given in the enclosed excerpt from the SWTP catalog. This unit was chosen because it is rugged, inexpensive, and has been on the market long enough for widespread use. For those who do not want to get involved in constructing a kit, used PR-40s are readily available. The printer used in developing the interface was bought from an ad in a computer club newsletter for $175. It turned out to be an early model, and had a defective printhead, so it was sent back to SWTP for repair. It came back with a new printhead, within ten days, and the electronics had been updated to the latest model; all for a charge of $24. Southwest sells the printer kit directly, or it may be bought through most Computer Stores.

SOFTWARE:

By using the IEEE-488 port on the PET, no software routines are required to drive the printer, since the PET Operating System fully supports this output. The PET treats peripherals on the IEEE port as files, as is explained in the Commodore booklet, "PET Communication With The Outside World." For example, to list a program in memory, you would type in:

OPEN 4,4:CMD 4:List   (then hit RETURN)

Translated, this means PET will open a file, designated number 4; and will output to device number 4 on the IEEE port. CMD is one of the two print commands when in output file mode, (the other is PRINT #). LIST, of course, causes the printer to produce a hard copy of the program in memory. Using the techniques outlined in the booklet, output can be transferred under program control to or from the printer and the screen (device 3), or the two cassettes (devices 1 and 2). This should enable the user, for example, to maintain a mailing list on cassette tape, print on the screen for editing, and output to the printer for mailing labels. As software is developed for this interface-printer system, it will be made available to users.

IDIOSYNCRACIES:

There are a couple of considerations which should be mentioned; the first is that since the printer only responds to a limited character set, (capital letters, numerals, and some punctuation), it ignores the PET graphics and editing commands. For example, here's a handy utility program for loading machine language routines into the PET;

PET CONNECTOR

COMPUTER PRODUCTS CATALOGUE

PR-40 PRINTER EXCERPT

automatically reverses it when it reaches the end of one of the two spools. This means you need only change ribbon when the printing becomes too light for easy legibility.

The Electronics

The electronic circuitry driving the forementioned print mechanism can vary from nothing but motor and solenoid drivers constantly serviced by the microcomputer to a fully self-contained hardware control unit with memory needing only 7 bit parallel ASCII data and a "data ready" strobe control line from the computer. This printer system fits into the latter catagory. The printer has it's own 40 character FIFO (first in—first out) memory allowing the computer to send character data at whatever speed it wishes. The entire line is printed upon receipt of a carriage return ($0D_{16}$) or automatically whenever the 40 character line buffer has been filled. All control characters with the exception of a carriage return are ignored by the printer. They are not stored in the FIFO line memory since they cannot be printed anyway. Repeated line feeds are initiated by sending repeated carriage return control commands. Since the printer prints upper case ASCII characters only, all lower case characters sent to the printer are transposed to their upper case equivalent before printing. The printer's line buffer memory is automatically cleared by a hardware power-up reset circuit when printer power is first applied. The printer's motor is triac controlled and is powered by a 120 VAC secondary on the power supply's power transformer. This not only provides power line isolation but allows the entire unit to be run on either 120 VAC or European 240 VAC power systems since the power transformer has two primary windings which may be either parallel or series connected.

The seven ASCII parallel data input lines and "data ready" and "data accepted" control lines are all TTL compatible. The inputs represent a maximum of two standard TTL loads while the "data accepted" output will drive ten standard TTL loads. Data is presented to the printer by storing the selected ASCII data on the seven data input lines and strobing the normally high (logic 1) "data ready" input line low. This line should go low (logic 0) for at least 1 microsecond and when it does the normally high "data accepted" will also go low. The character is not actually loaded until the "data ready" input is returned to its normally high stage. The "data accepted" line will then normally return high as well, indicating that the character has been loaded. However, when loading the 40th character on a print line or a carriage return command, this "data accepted" line will not return high until the character data has been printed and the printer memory is ready for more data. The printer will ignor all data sent to it while the "data accepted" line is low. So you will usually want to make sure the "data accepted" output line is high before sending the printer data to be printed.

If you are careful not to output data faster than one character per microsecond and allow a minimum one second delay before sending data after sending a carriage return or the 40th character of each line then you may avoid using the "data accepted" line altogether. However, using the "data accepted" line will give your system the fastest possible print speed.

The PR-40 Alphanumeric Printer is available in kit form only and includes the print mechanism, chassis, circuit boards, components, power supply, assembly instructions, one ribbon and one roll of paper:

PR-40   Alphanumeric Printer Kit . . . . ppd Continental U.S. $250.00
PR-4R   extra ribbon for above printer. . . . . ppd Continental U.S. $ 5.00

Those customers using the PR-40 printer with the SWTPC 6800 Computer System will need one of the computer's MP-L parallel interface option boards to drive it.

# MP-LA   SWTPC 6800 Parallel Interface Option Kit . . . . . ppd Continental U.S. $ 35.00

PR-40B CIRCUIT BOARD

PR-40A CIRCUIT BOARD
to first assemble the PR-40A board, then the PR-40B baord, then complete the
unit by installing the chassis components and completing the wiring. The assem-
bly instructions have been written in this sequence.

PR-40A PC Board Assembly

NOTE: Since all of the holes on the PR-40A PC board have been plated thru,
it is only necessary to solder the components from the bottom side of the board,
unless otherwise noted. The plating provides the electrical connection from
the "BOTTOM" to the "TOP" foil of each hole. Unless otherwise noted it is im-
portant that none of the connections be soldered until all of the components of
each group have been installed on the board. This makes it much easier to in-
terchange components if a mistake is made during assembly. Be sure to use a low
wattage iron (not a gun) with a small tip. Do not use acid core solder or any
type of paste flux. We will not guarantee or repair any kit on which either
product has been used. Use only the solder supplied with the kit or a 60/40
alloy resin core equivalent. Remember all of the connections are soldered on
the bottom side of the board only. The plated-thru holes provide the elect-
rical connection to the top foil.

( ) Before installing any parts on the PR-40A circuit board, check both sides
     of the board over carefully for incomplete etching and foil "bridges" or
     "breaks". It is unlikely that you will find any but should there be one
     especially on the "TOP" side of the board it will be very hard to locate
     and correct after all of the components have been installed on the board.

( ) Attach all of the resistors to the baord. As with all other components un-
     less noted, use the parts list and component layout drawing to locate each
     part and install from the board "TOP" side of the board bending the leads along
     the "BOTTOM" side of the board and trimming so that 1/16" to 1/8" of wire
     remains. Solder. You should have one 1M ohm resistor left over.

( ) Install all of the capacitors on the board. Be sure to orient the electro-
     lytic capacitors correctly. The polarity is indicated on the component
     layout drawing. Solder.

( ) Install integrated circuits IC3 thru IC17 on the circuit board. The in-
     tegrated circuits must be turned to match the outlines shown on the com-
     ponent layout drawing. Solder.

( ) Install fuses F1 thru F7 on the circuit board. Solder.

( ) Install the diodes and transistors on the circuit board. Transistors Q1
     thru Q7 must be mounted vertically with the bottoms of the transistors
     about 3/16" above the top of the board. These components must be turned
     to match the outlines shown on the component layout drawing. Solder.

( ) Insert the twelve male PC mount pins into the 12 pin Molex female connector
     shell. The pins are inserted from the back or numbered side of the con-
     nector. Orient the shell as shown in the component layout drawing and
     mount it in the J1 connector position. Solder.

( ) Insert female receptacle J2 into the PC board making sure to orient it as
     shown in the component layout drawing. The small notches on the inside

- 2 -

SWTPC PR-40 Alphanumeric Printer Assembly Instructions

The SWTPC PR-40 Printer kit is a 5 X 7 dot matrix impact printer similar
in operation to the well known Centronics printers. It prints the 64 character
upper case ASCII set with 40 characters/line at a rate of 75 lines/minute on
standard 3 7/8" wide rolls of adding machine paper. One complete line is print-
ed at a time from an internal forty character line buffer memory. Printing
takes place either on receipt of a carriage return or automatically whenever the
line buffer memory is filled.

The printer can accept character data as fast as one character per micro-
second or as slow as you wish to send it. The printer's seven parallel data
lines are TTL compatible and may be enabled by a single "data ready" control
line or by separate "data ready" and "data accepted" handshake control lines.
This universal approach makes the printer compatible with all computer and
terminal systems having an eight bit parallel interface; including of course
the MITS 8800 and SWTPC 6800 computer systems just to mention a few.

The printer mechanism is attached to a black anodized aluminum chassis
with front trim panel which houses the unit's circuitry including its own
120/240 VAC 50 to 60 Hz power supply. This makes the printer's overall di-
mentions 9 5/8" wide X 10 1/2" deep X 8 3/4" high.

Each unit is shipped with one ribbon and one roll of paper. Extra rib-
bons are available from us while the standard adding machine paper may be
purchased in office supply stores.

Caution

When handling the print mechanism itself you must make absolutely sure
not to try to rotate the large plastic cylinder that moves the head. If this
cylinder is rotated so the top is turned toward the front of the printer, it
may bend the arm on the roller cam microswitch on the right hand side of the
mechanism which will not only damage the switch but will prevent the printer
from operating.

Note

The print mechanism you receive may not have the paper roll holder in-
stalled. If so, it along with the mounting hardware will probably be contained
within a separate bag. The paper roll holder is secured to the back of the
print mechanism with four screws.

Assembling the Unit

The electronics for the printer are constructed on two printed circuit
boards. The larger of the two is the PR-40A and contains all of the logic
necessary to drive the print mechanism. The smaller board is the PR-40B and
contains mostly power supply circuitry. When assembling the printer it is best

- 1 -

( ) Attach all of the resistors to the board excluding resistor R6. As with
all other components unless noted, use the parts list and component layout
drawing to locate each part and install from the "TOP" side of the board
bending the leads along the "BOTTOM" side of the board and trimming so that
1/16" to 1/8" of wire remains. Solder.

( ) Install all of the capacitors on the board excluding electrolytic capacitor
C4. Be sure to orient the electrolytic capacitors correctly. The polarity
is indicated on the component layout drawing. Note the two set of holes for
C3 to accomodate two different size capacitors - use the correct set depend-
ing on your capacitor. Solder.

( ) Install transistor Q1 on the PC board. The transistor must be turned to
match the outline on the component layout drawing. Solder.

( ) Install transistor Q2 on the PC board. The transistor must be oriented so
that its flat side is against the circuit board and should be secured with
a #4-40 X 1/4" screw.

( ) Install all of the diodes on the PC board making sure to orient each as
shown in the component layout drawing. Solder.

( ) Install all of the male PC type pins in female connector shells J1 and J2
from the numbered side of the connector. Then install each connector in its
proper location oriented as shown in the component layout drawing. Solder.

( ) Now that all of the components have been installed on the board, double check
to make sure all have been installed correctly in their proper location.

( ) Check very carefully to make sure that all connections have been soldered..
It is very easy to miss some connections when soldering which can really
cause some hard to find problems later during checkout. Also look for solder
"bridges" and "cold" solder joints which are another common problem.

This completes the assembly of the PR-40B circuit board.

Chassis Assembly

( ) Some of the print mechanisms we are supplying have two mounting holes on the
bottom while others have three. Install the appropiate number of mounting
screws thru the proper holes on the chassis by running a number 6 - 32 X 1/2"
screw thru the chassis from the inside followed by a lockwasher and #6 - 32
nut. The printer mechanism itself will be attached to these screws at a
later time.

( ) Snap the large plastic bushing into the chassis from the outside of the chassis.

( ) Attach fuseholder F1 to the chassis using a #6 - 32 X 3/8" screw, lockwasher
and nut. Orient the fuseholder as shown in the wiring diagrams.

( ) Scrape away the anodizing around the mouting hole for TS-1 on the inside of the
PR-40 chassis. Scraping away the anodizing insures electrical contact between
the terminal strip and the chassis. Attach lug strip TS-1 to the chassis us-
ing a #6 - 32 X 1/4" screw, lockwashers and nut. Sandwich one lockwasher
between the terminal strip and the chassis. Orient the lug strip as shown in
the wiring diagram.

of the connector must point toward the edge of the board as shown in the component layout drawing. Solder.

( ) Insert Molex receptacle J3 into the PC board making sure to orient it as shown in the component layout drawing. The notches on the connector must point toward the edge of the PC board as shown in the component layout drawing. Solder.

( ) Insert Molex receptacle J4 into the PC board making sure to orient it as shown in the component layout drawing. The notches on the connector must point toward the edge of the PC board as shown in the component layout drawing. Solder.

NOTE: MOS integrated circuits are susceptable to damage by static electricity. Although some degree of protection is provided internally within the integrated circuits, their cost demands the utmost in care. Before opening and/or installing any MOS integraged circuits you should ground your body and all metallic tools coming into contact with the leads, thru a 1 M ohm 1/4 watt resistor (supplied with the kit). The ground must be an "earth" ground such as a water pipe, and not the circuit board ground. As for the connection to your body, attach a clip lead to your watch or metal ID bracelet. Make absolutely sure you have the 1 Meg ohm resistor connected between you and the "earth" ground, otherwise you will be creating a dangerous shock hazard. Avoid touching the leads of the integrated circuits any more than necessary when installing them, even if you are grounded. On those MOS IC's being soldered in place, the tip of the soldering iron should be grounded as well (separately from your body ground) either with or without a 1 Meg ohm resistor. Most soldering irons having a three prong line cord plug already have a grounded tip. Static electricity should be an important consideration in cold, dry environments. It is less of a problem when it is warm and humid.

( ) Install MOS integrated circuits IC1 and IC2 following the precautions given in the preceding section. As each is installed, make sure it is down firmly against the board before soldering all of its leads. Be very careful to install each in its correct position. Do not bend the leads on the back side of the board. Doing so makes it very difficult to remove the integrated circuits should replacement ever be necessary. The "dot" on the end of the package is used for orientation purposes and must match with that shown on the component layout drawing for each of the IC's.

( ) Working from the "TOP" side of the circuit board, fill in all of the feed-thru's with molten solder. The feed-thru's are those unused holes on the board whose internal plating connects the "TOP" and "BOTTOM" circuit connections. Filling these feed-thru's with molten solder guarantees the integrity of the connections and increases the current handling capability.

( ) Now that all of the components have been installed on the board, double check to make sure all have been installed correctly in their proper location.

( ) Check very carefully to make sure that all connections have been soldered. It is very easy to miss some connections when soldering which can really cause some hard to find problems later during check out. Also look for solder "bridges" and "cold" solder joints which are another common problem.

This completes the assembly of the PR-40A circuit board.

( ) Attach and solder three 16" pieces of #24 (light) gauge hookup to each of the
    three switch-terminals on the roller cam microswitch located on the right
    hand side of the printer mechanism. On the opposite end of the upper lug's
    wire, attach a male pin. Attach a female pin to the unconnected end of the
    remaining two lug wires. Solder.

( ) Insert each of the pins into the specified pin location of a six pin Molex
    male plug using the table below. The pins must be installed from the back
    or numbered side of the connector:

ROLLER CAM SWITCH LUG	CONNECTOR PIN #
upper	3
middle	1
lower	2

( ) Complete wiring steps 1 thru 4 of the wiring table if you will be operating
    the printer on 120 VAC. For 240 VAC, 50 Hz operation, skip wiring steps
    2 and 3 and instead connect together and insulate transformer T1's brown
    and black-red wires. Then connect T1's remaining black and brown-white
    wires just as described in the wiring table steps 1 and 4.

( ) Complete wiring steps 5 thru 10 of the wiring table and then snap fuse F1
    into place.

( ) Complete wiring steps 11 thru 34 of the wiring table. A female connector
    pin will be attached to one end of each of the wires. Make absolutely sure
    each pin is installed correctly into the specified hole of the correct connector
    block, since the pins cannot be removed after installation. The pins must
    be installed from the back or numbered side of the connector. Take note
    that J1 on the PR40B board is a 15 pin male connector block while J1 on
    the PR40A baord is a 12 pin male connector block.

( ) Check to make sure that all electrical connections have been soldered. Cut
    off any extra length of the tabs on C4 if necessary.

( ) Snap the two PC boards into the chassis. The larger PR40A board should be
    oriented so the upright transistors are adjacent the power transformer,
    while the smaller PR40B board should be oriented so the 15 pin connector is
    near the power transformer.

( ) Plug each of the J1 connectors onto their respective mates.

( ) Set the printer chassis upside down (components exposed) and set the print
    mechanism itself right next to it. Connect the connector from the print
    mechanism's motor wires to the PR40B's J2 connector block.

( ) Attach the connector from the print mechanism's roller cam microswitch wires
    to the PR40A's J3 connector block.

Installing the Ribbon and Paper Roll

    The paper roll is installed by pressing the plastic roll holder thru the
center of the paper and placing the spool on the printer so the paper pulls from
the inside back of the printer. This allows the paper to contact the paper guides
at all times thus centering the paper for printing. Feed the paper thru the
guides   adjacent the paper roll and advance the platten.

- 6 -

( ) Attach transformer T1 to the chassis using four #8-32 X 3/8" screws, falt-
     washiers and nuts. Run the screws thru the outisde of thechassis, place a
     flatwasher between the inside of the chassis and the transformer leg, place
     another flatwasher on the top of the leg and secure with a #8-32 nut and
     lockwasher. Orient the transformer so the side with the green secondary
     leads is toward the inside of the chassis.

( ) Snap the eight PC board standoffs into their respective holes from the in-
     side of the chassis.

( ) Attach the two large capacitor clamps to the chassis using #6-32 X 1/4"
     finishing screws, lockwashers and nuts. Orient the clamps as shown in the
     wiring diagrams.

( ) Snap PR40B's electrolytic capacitor C4 into place in the two capacitor
     clamps on the front of the chassis. Be sure to orient the capacitor as
     shown in the wiring diagrams. The negative terminal of the capacitor must
     be nearer the bottom of the chassis.

( ) Attach toggle switch S1 to the chassis using the supplied finishing washer
     and nut. Orient the switch as shown in the wiring diagram.

( ) Crimp the strain relief onto the line cord at a point about six inches
     from the end of the cord using a pair of pliers. While compressing the
     strain relief insert the short end of the line cord and the strain relief
     into the hole provided on the back of the chassis and release.

Attaching Connectors to the Print Mechanism

     The print mechanism is supplied with two connectors installed, one for
the print head and one for the printer motor. The connector for the print head
is a fifteen pin AMP connector and will mate to a connector located on the PR-40A
board. The connector for the printer motor is a nine pin AMP connector and must
be cut off right at the connector so that another connector may be installed in
its place.

( ) Cut off the nine pin motor connector for the print mechanism right at the
     connector.

( ) You should note that the print mechanism motor is divided into two distinc-
     tive halves. The inner half has one black and one white wire coming out
     of it and the outer half also has one black and one white wire coming out
     of it. Attach and solder a female connector pin to the end of each of the
     four wires. Insert the wires into the respective pins of a six pin Molex
     male connector as listed below:

MOTOR WIRE	CONNECTOR PIN #
inside white	1
outside white	3
outside black	4
inside black	6

     The word inside refers to being nearest the body of the printer while out-
     side is farthest away. The wires are each electrically dependent and **must**
     be connected exactly as listed in the preceeding table for the printer
     motor to run correctly.

If you will be using the PR-40 Printer with the SWTPC 6800 Computer System, you will need to drive it with the output half of an MP-L option on the SWTPC 6800 Computer System. Connections should be made between the two as shown in the PR-40/SWTPC 6800 Interconnection drawing. When writing programs to drive the PR-40 printer with the SWTPC 6800 Computer System, it will be necessary to first configure the 6820 peripheral interface adaptor integrated circuit on the MP-L option of the SWTPC 6800 as in the diagnostic and then use an output character routine similar to that used in the PRNTST-1 diagnostic.

Checkout and Adjustment

For the initial testing of your PR-40 disconnect the printer solenoids by pulling loose J2 on the PR40A board if you have the solenoids connected. In order to checkout the printer you should use an analog type DC voltmeter having a 0-10V scale. (Most digital meters give false readings for this particular application). Connect the negative (-) end of your meter to the PR40's chassis or PC board ground and hook a 4.7K ohm 1/2 watt resistor (supplied) between the + and - terminals of your meter. Turn on the power and connect the positive meter probe (with the 4.7K resistor attached) to the collector of Q1 on the PR-40A board (the metal part of the case with the mounting hole in it). The voltage should read very low and go up as you initiate your PRNTST diagnostic program. Also note that the print motor should start up and move the head although no printing will occur. If the voltage does not rise recheck your program. The voltage should rise to anywhere between 1 and 6 volts depending on the setting of the density control. Check each of the seven transistors for this voltage. If the voltage goes beyond about 6 volts recheck your circuit board for mistakes - DO NOT HOOK UP THE SOLENOIDS UNTIL THE PROBLEM IS CORRECTED.

After you have verfied that all voltages look OK switch the printer off and connect J2. Re-load your diagnostic and switch the printer on. Running your diagnostic should activate the printing mechanism and printing should start. You can now adjust the line length and print density. Adjust R25 for the print intensity most desirable. The line width can then be adjusted by R17. Note that if the width is extended too far the characters on the right edge will be much narrower than normal. After the line width has been adjusted the paper can be centered by moving the two white plastic guides on the round bar underneath the platen at the rear of the mechanism. If necessary, the entire paper carrier can be moved slightly by loosening the four screws holding it to the main mechanism and sliding it to one side or the other as necessary.

The Printer Mechanics

The entire design is based on a remarkably simple and reliable print mechanism. The printed characters are formed by moving the print head horizonally across the paper while selectively energizing solenoid driven print wires on the head which strike an inked ribbon and imprint dots on standard adding machine paper. All seven of these solenoid driven print wires converge at the tip of the print head in a vertical line which is perpendicular to the horizonal direction of movement of the print head. By selectively firing the print wires,

The ribbon is installed by first orienting the spools so the ribbon is fed and spooled from the outside of the spools and then snapping the spools into place so the ribbon is routed inside the tensioner and looped around the guides on both sides of the platten. The ribbon is self-reversing so it doesn't matter which spool is placed where. After installing the ribbon be sure that each ribbon spool will turn freely on its respective shaft. If a spool is excessively tight on a shaft sanding the shaft slighty with sandpaper should help. If the binding is being caused by the two springs on the spindle that hold the spool in place a small washer can be placed between the bottom of the spindle and the mechanism that it is attached to. This will allow the spool to ride lower on the spindle.

You are now in a position to test and set the line length and print intensity adjustments on the printer. By having everything exposed as you do now, adjustments and troubleshooting will be considerably easier. Once the unit has been calibrated and thoroughly tested, as described later in the instructions, the print mechanism can be disconnected and reinstalled and secured on the top of the printer chassis using #6-32 nuts and lockwashers. All of the wires for the print mechanism are then run thru the large bushing on the top of the printer chassis. The I/O cable feeding the printer is also run out of this large bushing so that the bottom of the printer may be closed with the perforated cover supplied with the kit. The cover is secured with #6-32 screws and tinnerman nuts which are also supplied with the kit. The four rubber feet should be attached to the outside of the cover about 1" in from each corner.

Wiring the Printer's Input Data Connector

The actual ASCII data fed to the printer is input thru connector J4 on the PR-40A board. In order to test and set the calibration controls on the printer, it will be necessary to load a diagnostic program into your computer system to feed data to the printer. The program should feed the printer continual, printable ASCII data. This will force the printer to print full 40 character lines which are necessary to set the line length trimmer resistor, R17 for symmetrical margins. Trimmer resistor R25 sets the print intensity and may be adjusted when printing any line length.

If you are using the PR-40 printer with the SWTPC 6800 Computer System you should use the PRNTST-1 diagnostic contained within this instruction set, otherwise you will need to write a program for your own specific computer system which performs similar functions. You may even feed the printer directly from an ASCII keyboard if you can live with not being able to read the line until a carriage return is entered. The keyboard must output a negative going "keypressed" strobe for direct compatibility with the PR-40 Printer.

The data connections to J4 on the PR-40A board should be made as follows:

J4 Pin #	Data Connection
1	ground
2	"data accepted" output – from printer
3	"data ready" from computer
4	ground
5	ASCII bit 5
6	ASCII bit 6

- 7 -
output   7   Bits , one strobe

strobe active low ; data loaded when strobe returns high

PR40 Connector   Signal
    J4 Pin   DB25

1	Gnd	6	Gnd
2	"data accepted" ; from printer	4	PA0
3	" data ready" ; strobe from comp. (D7)	11	PB7
4	Gnd		
5	D5	25	PB5
6	D6	10	PB6
7	NC		
8	D3	23	PB3
9	D4	24	PB4
10	D0	20	PB0
11	D1	21	PB1
12	D2	22	PB2

The Electronics

The electronic circuitry driving the forementioned print mechanism can vary from nothing but motor and solenoid drivers constantly serviced by the microcomputer to a fully self-contained hardware control unit with memory needing only 7 bit parallel ASCII data and a "data ready" strobe control line from the computer. This printer system fits into the latter catagory. The printer has it's own 40 character FIFO (first in - first out) memory allowing the computer to send character data at whatever speed it wishes. The entire line is printed upon receipt of a carriage return ($0D_{16}$) or automatically whenever the 40 character line buffer has been filled. All control characters with the exception of a carriage return are ignored by the printer . They are not stored in the FIFO line memory since they cannot be printed anyway. Repeated line feeds are inititated by sending repeated carriage return control commands. Since the printer prints upper case ASCII characters only, all lower case characters sent to the printer are transposed to their upper case equivalent before printing. The printer's line buffer memory is automatically cleared by a hardware power-up reset circuit when printer power is first applied. The printer's motor is triac controlled and is powered by a 120 VAC secondary on the power supply's power transformer. This not only provides power line isolation but allows the entire unit to be run on either 120 VAC or European 240 VAC power systems since the power transformer has two primary windings which may be either parallel or series connected.

The seven ASCII parallel data input lines and "data ready" and "data accepted" control lines are all TTL compatible. The inputs represent a maximum of two standard TTL loads while the "data accepted" output will drive ten standard TTL loads. Data is presented to the printer by storing the selected ASCII data on the seven data input lines and strobing the normally high (logic 1) "data ready" input line low. This line should go low (logic 0) for at least 1 microsecond and when it does the normally high "data accepted" will also go low. The character is not actually loaded until the "data ready" input is returned to its normally high state. The "data accepted" line will then normally return high as well, indicating that the character has been loaded. However, when loading the 40th character on a print line or a carriage return command this "data accepted" line will not return high until the character data has been printed and the printer memory is ready for more data. The printer will ignor all data sent to it while the "data accepted" line is low. So you will usually want to make sure the "data accepted" output line is high before sending the printer data to be printed.

If you are careful not to output data faster than one character per microsecond and allow a minimum one second delay before sending data after sending a carriage return or the 40th character of each line then you may avoid using the "data accepted" line altogether. However, using the "data accepted" line will give your system the fastest possible print speed.

How It Works

All ASCII character data is presented to the FIFO memory, IC1 thru hex inverter/buffer IC12. NAND gate IC14A makes any necessary conversions from lower to upper case characters. 8 input NAND gate IC13 monitors the incoming ASCII data in search of a carriage return ($0D_{16}$ or $0000\ 1101_2$) control command. If it decodes a carriage return it will prepare normally high control flip-flop IC8A

5 dot wide X 7 dot high characters are printed as the print head moves across the paper. A one dot time spacing is left for separation between the printed characters.

This method of printing characters is not new but the method of moving this wire impact print head is unique. Rather than using dual motors, clutches timing bars and the other hardware usually associated with this type of print head, this printer rotates a long cylinder just beneath the print head. The length of the cylinder itself is a little longer than the head's printing width on the paper. The cylinder has a uniform single cyclic zig-zag track formed on its outer circumference, running from the left side of the cylinder to the right side then back to the left again. A small projection on the bottom of the print head rides in this track so that as the cylinder rotates the print head moves back and forth from left to right. This technique moves the print head across the paper at a constant velocity except for the extreme ends, where nothing is printed anyway. This approach greatly simplifies the electronics needed to drive the printer since no head positioning circuitry is necessary. The cylinder itself is turned by an AC motor on the lower right hand side of the print mechanism. A small ribbed nylon belt interconnecting the two rides on gear teeth of both the motor and cylinder. Also attached to the right side of the cylinder is a cam that actuates a roller arm micro-switch riding on the cam. This is how the printer's electronic circuitry senses the "start of line" position of the print head. On the left side of the cylinder is an eccentric driven pawl arm that advances the paper one line for each revolution of the cylinder which is the same as one cycle of the print head.

Let's go thru a cyclic operation of a printed line where we will first assume the head is in rest position just left of center. When a line print command is initiated by the control circuitry, the motor starts and the head begins to move from the center position toward the far left side of the printer where the head reverses direction. This non-print dead zone gives the motor, cylinder, and print head time to attain full speed. As the head begins its movement from left to right, the cam actuated micro-switch opens telling the electronic circuitry to start outputting character forming solenoid driving pulses. Somewhere before the print head reaches the far right hand edge of the paper the solenoid pulses will cease while the head continues to move. When the head reaches the right end of its travel, it will reverse direction and begin to move back toward the center of the printer. During this return movement, the pawl arm will rotate the platen one line for the line feed. The motor is then turned off just to the left of center where it started originally. Character data is not accepted by the printer's circuitry during an actual print cycle, however feeding continual print data from a computer to the printer may take place so fast that the print motor may never appear to stop between repeatedly printed lines although it actually does.

The operation of printing ribbon used on the unit is also amazingly simple. A ratchet technique not only advances the ribbon incrementally for each cycle of the print head but automatically reverses it when it reaches the end of one of the two spools. This means you need only change the ribbon when the printing become too light for easy legibility.
to go low on the falling edge of the "data ready" (input strobe) control signal.
NOR gate IC15A decodes all control characters and along with IC15B inhibits any
control characters from being loaded into the FIFO memory. NAND gate IC9A is
responsible for generating the "data accepted" output whenever data has been
accepted by the FIFO memeory or acknowledged by the control character decode
logic. It also inhibits the "data accepted" output while the printer is in the
process of printing a line.

Control flip-flop IC8A's Q output is high when the printer is in the idle
state. A FIFO full signal decoded by NOR gate IC15D or a decoded carriage re-
turn command by IC13 resets this flip-flop low which turns the printer's motor
on thru transistors Q1 and Q2 located on the power supply board which starts a
line print sequence.

When the print head advances to the "start of line" position, the roller
arm microswitch changes states which flips RS latch NAND gate IC11D low which
allows free running oscillator IC10 to feed divide by 2 flip-flop, IC8B. This
divide by 2 feeds both the dot counter, IC4, and solenoid timer IC6. This sole-
noid timer is used to set the "ON" time of the printer's solenoids. If set too
long, the solenoids will overheat, if set too short, the printed lines will be
too light. An "ON" time duration of 400 microseconds is the best compromise
setting. Decade counter IC4 has its B and C outputs tied back to its zero reset
inputs forcing it to become a modulo 6 counter. As the counter progresses from
0 to 4 inclusive, the selected character lines are decoded by the ROM, IC2 using
the ASCII data fed to it by FIFO memory, IC1, and fed onto the solenoids thru
buffers IC3 and IC7 and Darlington drivers Q1 and Q7. Counter state 5 is de-
coded by the ROM as a blank for the one dot space necessary to separate the
printed characters. In the latter phase of the five count the FIFO is shifted,
the counter resets, and the sequence repeats. When the FIFO finally empties,
the ROM is disabled and blanks the output for the rest of the print cycle. When
the still moving print head reaches it's normal "rest" position, the roller arm
microswitch again changes states   This time RS latch NAND gate IC11C flips low
setting control flip-flop IC8A back to normally high state.

Timer IC5 is a power up clear circuit which empties the FIFO memory and helps
prevent random firing of the print solenoids during power up.

Note

When turning the printer off it is best to use the toggle switch on the
front of the printer chassis. This toggle switch not only interrupts the 120
VAC being delivered to the power transformer on the printer but also disables the
40 VDC line feeding the solenoids. It is necessary to break this line while the
DC voltages in the system are bleeding down in order to prevent the print solenoids
from randomly firing and printing a vertical line on the paper.

In Case of Problems

In case of problems, the best procedure is to remove power and recheck all
assembly steps. Since you are probably feeding the printer with a computer system,
don't rule out a possibility of a problem either in the interconnection between
the two or in the program driving the printer.

As far as the printer itself is concerned, check the voltages on the PR-40B
board to make sure the DC voltages are within 10% of their specified ratings as
shown on the PR-40B schematic. Other than this the only thing you can do is go
thru the PR-40A board components one by one until you can pin down the source of
the problem.

If you still cannot find the problem or do not wish to service the unit
yourself, repair services are available from us at a cost of $20.00 labor plus parts.

To set the printer's line width adjustment, you should use Mikbug ^{R} to change the data in memory locations A$\emptyset$56 and A$\emptyset$65 from $\emptyset$D$_{16}$ to $\emptyset\emptyset$16. This will eliminate the transmitted carriage returns and force the printer to print a full 40 column line. The line width control should then be adjusted for symmetrical margins. The characters will still be printed sequentially but will not be identical from line to line.

DO NOT operate the printer more than a minute or so while running this diagnostic. Continuous printing of full length lines with no spacing between characters overheats the solenoids on the print mechanism which may decrease its operating life.

If you are using the SWTPC PR-40 printer with the SWTPC 6800 Computer System, you may use the OUTCHR subroutine listed from address A$\emptyset$14 thru A$\emptyset$24 in the PRNTST diagnostic within your own program for outputting characters to the printer. The index register must be loaded with the starting address of the MP-L Parallel Interface board feeding the printer. The character to be printed must be loaded into accumulator A and the contents of accumulator B are destroyed during the subroutine.

Never install or remove the interface board when the system is powered up. Doing so is not only hazardous to the equipment, but bypasses the normal power-up sequence required by the internal registers within the 6820 integrated circuit in order to guarantee proper operation.

Mikbug ^{R} is a registered trademark of Motorola Inc.

This printer diagnostic has been written to test and/or debug the SWTPC PR-40 printer when it has been interfaced to the SWTPC 6800 Computer System thru one of the MP-L parallel interface boards. It is assumed that before loading this program, the rest of the system is functioning normally with no problems. The program itself uses 60_{10} words and is loaded within the 128 word RAM used by the MIKBUG ^{R} operating system on the MP-A Microprocessor/ System Board. A program may reside in external RAM memory simultaneosuly with the diagnostic loaded within the 128 word RAM, or the diagnostic may be run with no MP-M memory boards installed on the system at all. The diagnostic may be loaded either from tape or instruction by instruction using MIKBUG ^{R} starting from address A014 thru A024 and then from address A048 thru A072. The address of the MP-L parallel interface board feeding the printer must be set using MIKBUG ^{R} to load the hexadecimal address of the selected port into memory locations A002 and A003 with the most significant byte going into A002 and the least significant byte going into A003. The starting address locations of the interface ports are given below:

Port		Address in Hex
I/O	#0	8000
I/O	#1	8004 (reserved for control interface)
I/O	#2	8008
I/O	#3	800C
I/O	#4	8010
I/O	#5	8014
I/O	#6	8018
I/O	#7	801C

Since the program counter is set when the program is initially loaded, the diagnostic is initiated as described in the "Go to User's Program" section of the Engineering Note 100. Once initiated, the program can be stopped only by depressing the "RESET" button. The program may then be re-started after resetting the program counter to A04A as described in the "Display contents of MPU registers Function" section of Engineering Note 100.

The diagnostic works by sending out an ASCII carriage return ($0D_{16}$) followed by ASCII characters 21_{16} thru $3F_{16}$ followed by a carriage return ($0D_{16}$), followed by ASCII characters 40_{16} thru 5E inclusive, repeating itself until stopped with the RESET switch.

Each character is output to the printer by first storing the ASCII character's bits 0 thru 6 on output lines 00 thru 06 of the selected MP-L Parallel Interface port, then bringing the normally high "Data Ready" line low via interface output control line C2 for at least one microsecond then returning the line high again. The data must be held stable on the interface output lines however until the printer acknowledges data receipt by bringing its normally high "Data Accepted" line momentarily low and then high again. This latter low to high transition signifies that the printer has accepted the character. The MP-L control line C1 fed by this line has been programmed to see the low to high "Data Accepted" transition and responds by allowing the program to output the next sequential ASCII character.
